GTS123 Introduction to Computers and Programming

Lab 9: Problem 4

Write a Python program to ask a user to input the user's height and weight and compute the user's body mass index (BMI):

$$\text{BMI} = \frac{weight}{height^2}$$

where weight and height are in the units of kilogram and meter, respectively. Assume that the user will always input positive numbers (i.e., no need to check the validation of the inputs). The program will use the following three functions.

- Write a function called UserInput() to ask a user to input the user's height and weight.
- Write a function called FindBMI(hh, ww) to compute the user's BMI according to the function's inputs hh and ww, which are height and weight, respectively. The BMI is stored in a variable UserBMI.
- Write a function called ShowBMI(MyBMI) to show the value of the user's BMI which is stored in the variable MyBMI.

The output should look similar to the following.

```
Input your weight (kilogram): 45
Input your height (meter): 1.61
The user BMI is 17.6
```

```
Input your weight (kilogram): 80
Input your height (meter): 1.75
The user BMI is 26.12
```

```
Input your weight (kilogram): 65
Input your height (meter): 1.80
The user BMI is 20.06
```

Note: To pass the test, your program must produce the exact output as shown above, including spaces and line breaks.
